1. Introduction

1.1. Purpose

This document explains the specifics of the smart parking system. The purpose of this project is to create a smart parking system that allows users to locate, reserve, and pay for parking spaces efficient. It defines the system's functionalities, constraints, and interfaces for development and evaluation.

1.2. Document Conventions

This document follows the IEEE 830 Software Requirements Specification standard and uses consistent terminology and formatting conventions to ensure clarity and precision. All mandatory requirements are expressed using the keyword “**shall**”, indicating a mandatory system. Optional or non-mandatory features may use terms such as “may” or “can”.

Functional requirements are labeled using the format Req-x, where x represents a unique identifier. Non-functional requirements are labeled as NF-x and are categorized based on quality attributes such as performance, security, and reliability.

1.3. Intended Audience and Reading Suggestions

This document is intended for developers, testers who will test the system, stakeholders who want to know more about their investment, and users that want to know more about how the system works.

Developer: Developers who intend to work on the system whether to improve, modify, or extend the system must consult the document to understand the requirements and ensure consistency across all development phases.

Stakeholders: Stakeholders and including customers review this document to know if the requirements aligns with their requirements and goals. They use this specification to ensure that the system fulfills its intended purpose and delivers the required functionality.

Tester: The tester uses this document to test if the implemented system satisfies all specified requirements. It serves as a reference for designing test cases and ensuring that the system behavior matches the defined requirements.

1.4. Product Scope

The Smart Parking System is designed to assist drivers in locating, reserving, and paying for parking spaces in an efficient and manner. The system provides real-time information about parking availability and enables users to reserve spots in advance, reducing the time spent searching for parking. The system also supports administrative functionality for managing parking spaces, including adding, updating, and removing parking data. Additionally, it integrates with an external payment system to handle secure transactions.

1.5. References

No references

2. Overall Description

2.1. Product Perspective

The Smart Parking System is a standalone application that operates as an interface between users and parking infrastructure. It interacts with a centralized database to manage details like availability and reservations. It also has an external payment system to process transactions more securely. It may also receive data from sensors or manual input for availability of the parking spots.

System consists of three parts.

- User Interface
- Admin Interface for managing data
- Backend system that communicates that handles data processing, reservations, and communication with external services

2.2. Product Features

The Smart Parking System provides the following main features:

- **Parking Search:** Users can search for available parking spaces based on location.
- **Real-Time Availability:** The system displays up-to-date information about parking spot availability.
- **Parking Reservation:** Users can reserve available parking spaces in advance.
- **Payment Processing:** The system enables users to pay for parking reservations through an integrated payment service.
- **Reservation Management:** Users can view, modify, or cancel their reservations.
- **Parking Management (Admin):** Administrators can add, update, or remove parking spaces and manage system data.

2.3. User Classes and Characteristics

1.User(driver): They use the application to find and reserve parking space. Also, they can pay using the same application.

- Basic knowledge of how to use applications
- Frequent Usage
- Simple to use

2.Administrators: They are the ones responsible for managing the app and maintaining parking system by parking space data and monitoring system activity.

- Technical knowledge on how to use system.
- Responsible for system updates and accuracy.
- Requires access to admin functions.

3.Payment System: Payment system is an external service that processes user transactions securely.

- No direct user interaction
- Handling financial transactions
- Ensures secure and reliable payment processing

2.4. Operating Environment

The smart parking system is a web based or a mobile app that requires internet connection. The system can be accessed from modern browsers such as Chrome, Firefox etc. while also be used as an app that can be downloaded from android and IOS app stores. The backend system is expected to run on a server environment with database support (e.g., MySQL or similar database systems).

2.5. Design and Implementation Constraints

- The system must support real-time data processing to ensure accurate parking availability information. This requires efficient data handling and reliable communication between the system and the database.
- The system must ensure secure processing of user data and payment transactions. Appropriate encryption and authentication mechanisms must be implemented to protect sensitive information.
- If parking sensors are used, the system must be compatible with their data formats and communication protocols.

- The system must operate within typical hardware limitations of user devices, such as smartphones and personal computers.

2.6. User Documentation

This document is the only one.

2.7. Assumptions and Dependencies

The development of the parking system has several assumptions and external dependencies. Firstly, it is assumed that users have access to internet-enabled devices such as smartphones or computers to interact with the system. The system depends on having a network connection to provide real time information about parking spaces and requests. The system relies on accurate and up-to-date parking data which also needs either automatically to update itself or manually changed by admins. The system requires an external payment service for transactions. It is also assumed that the system database is properly maintained
